Water Hardness

What Makes Up Hard Water?
Hard water contains high levels of dissolved calcium and magnesium ions. Calcium and magnesium occur naturally in soils. As groundwater or surface water comes into contact with these minerals, they may dissolve and enter the water supply. Calcium and magnesium help give water a pleasant taste and are necessary for our health. A small portion of our necessary dietary intake of calcium and magnesium comes from the water we drink.

Drinking Water Regulations
The Environmental Protection Agency (EPA) has developed the National Primary Drinking Water Regulations with enforceable standards on the amount of contaminants allowed in drinking water. These standards protect the public from contaminants that may pose a risk to human health.
All public water providers must meet requirements of these standards when supplying water to their customers.

In addition, the EPA has a set of standards known as the National Secondary Drinking Water Regulations. These standards are recommended guidelines that water providers can follow, but the standards are not enforceable. Substances found on this list are not harmful to human health, but may cause unpleasant changes in taste, odor and color.

Calcium and Magnesium
The EPA has not placed calcium or magnesium on either list. Their presence in drinking water is important because both calcium and magnesium are essential to health.

This link is to a complete list of EPA’s Primary and Secondary Drinking Water Regulations.

How Water Hardness is Classified

Water hardness is measured in the laboratory by the amount of calcium carbonate present. Although there is no set standard for the classification of water hardness, the following chart provides generally accepted classifications based on the concentration of calcium carbonate.

<table>
<thead>
<tr>
<th>Concentration in (mg/L)</th>
<th>Classification</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 to 60</td>
<td>Soft</td>
</tr>
<tr>
<td>61 to 120</td>
<td>Moderately Hard</td>
</tr>
<tr>
<td>120 to 180</td>
<td>Hard</td>
</tr>
<tr>
<td>More than 180</td>
<td>Very Hard</td>
</tr>
</tbody>
</table>

Mineral Deposits

Water that is classified as hard will leave mineral deposits on faucets and dishes, and may have a salty taste, but will not negatively affect human health. Some parts of the country have very hard water with typical concentrations of calcium carbonate ranging from 200 to 300 mg/L in drinking water.

Groundwater in Colorado

Colorado’s groundwater supplies are naturally high in calcium and magnesium ions, so groundwater is usually classified as being hard. Conversely, surface water sources contain lower concentrations of hardness ions. Therefore, any time a water provider has to switch supplies from surface water to groundwater, or increase the ratio of groundwater to surface water, customers may notice mineral deposits on dishes and changes in taste. Water providers can provide tips to manage these aesthetic changes such as using vinegar to remove hard water deposits on faucets or dishes.
